ShadowKit

& AgentBoard · demo: ShadowDAO

Vote in the shadows.
Execute in the light.

Zero-knowledge, AI-agent **governance infrastructure for Stellar**. Members vote in total privacy — who voted, how, and how much weight, all hidden — and the result stays **sealed until the deadline**. At close, an autonomous AI agent executes the decision on-chain, bounded by a policy it **mathematically cannot break**.

● PRIVATE & SEALED

● AUTONOMOUS AGENT

● ON-CHAIN SAFETY LOCK

STATUS

Live demo loop ✓

Governance that stays private — and acts on its own.

Today, on-chain voting is a glass box: everyone sees who voted, how, and how much they hold — and whoever holds the most can watch the live tally and swing it at the last second. Then, even after a vote passes, a human still has to manually sign off to make anything happen. **ShadowKit** removes both problems at once.

Private & sealed

Zero-knowledge proofs hide identity, choice, and weight. Timelock encryption keeps the tally invisible until close.

Autonomous

When voting closes, an AI agent reads the result and executes the on-chain action itself — no human approval needed.

Unbreakable

The agent's spending is gated on-chain. Even a hallucinating AI literally cannot move funds the vote didn't approve.

IN ONE SENTENCE

ShadowKit lets any DAO **vote in complete privacy**, keeps the outcome **sealed until the deadline**, and lets an **autonomous agent** carry out the decision — all secured by math, not middlemen.

It ships as **infrastructure** — an SDK and middleware any Stellar project can adopt — not a one-off app. The sample treasury, **ShadowDAO**, is just the showroom.

Web3 voting is public, gameable, and slow to act.

Three cracks in how decentralized communities decide and execute today — each one a reason people don't participate, or don't trust the outcome.

The glass-box ballot

On-chain votes are public by default. Small holders are exposed to whales, rival DAOs, and analytics firms who can see — and pressure — every choice. So many simply **don't vote at all**.

The bandwagon trap

When the running tally is visible, a whale can **wait, watch, and swing** the result at the last second. Live results invite last-minute manipulation and herd behavior — the loudest money wins.

The 3am multisig

Even after a vote passes, execution waits on humans to manually co-sign a multisig. It's **slow, centralized, and fragile** — a single missing signer can stall a decision the community already made.

The result: **low participation, manipulable outcomes, and execution that depends on the very middlemen decentralization was meant to remove.**

Three pillars, one autonomous loop.

Each pillar maps to a hackathon track — and together they make a vote that is private, fair, and self-executing. Plain-language first, real technology underneath.

PILLAR 01

● HACK PRIVACY

Private, sealed voting

Like a sealed ballot box the organizers themselves can't peek into — and no one can see who's winning until the timer hits zero. Identity, choice, and voting weight all stay hidden.

Under the hood: Groth16 zk-SNARKs verified **on-chain** (BLS12-381) · nullifiers stop double-voting · **drand** **timeLock** encryption seals the tally until close.

PILLAR 02

● HACK AGENTIC

Autonomous agent execution

The community decides; a tireless robot treasurer carries it out the instant voting closes — picking the best way to execute within the approved budget. No multisig phone-tree at 3am.

Under the hood: LLM-planned (Google **Gemini**) slippage / routing / timing · **session-key** signing · pays per-call for live market data via **x402**.

PILLAR 03

● THE SAFETY LOCK

The math lock

Even if the AI hallucinates or goes rogue, the blockchain itself **refuses** any move the community didn't approve — wrong amount, wrong target, wrong asset, or a vote that never passed.

Under the hood: an OpenZeppelin **Smart Account** policy enforces approved + capped + single-shot + correct target/asset on every transaction.

One proposal, start to finish.

The exact flow that runs live in the demo — the narrative spine for a pitch deck. A treasury proposal goes from a private vote to a fully autonomous on-chain swap, with no human ever touching the execution.

- 1  **Connect**
A member signs in with a **passkey** — no seed phrase, no extension friction. Face or fingerprint, done.
- 2  **Proposal goes live**
"Swap 15,000 USDC → XLM" opens with a voting deadline. A countdown starts ticking.
- 3  **Private vote**
In the browser, a **zero-knowledge proof** is built and the vote is **timelock-encrypted** to the deadline. Choice and weight never leak.
- 4  **Sealed on-chain**
The contract verifies each proof and stores the sealed vote. The UI shows only "N votes cast · results hidden" + countdown. **No one can see who's winning.**
- 5  **Reveal at the deadline**
The **drand beacon** unlocks the votes. The weighted tally is computed and verified on-chain — the **first time anyone** sees the result.
- 6  **The agent acts**
On quorum, the AI agent buys market data, plans the swap **within the approved cap**, and signs. The on-chain policy checks every condition before allowing it.
- 7  **Done — on-chain & live**
The swap executes on a Stellar DEX; the treasury updates in real time; AgentBoard's terminal streams the agent's reasoning. **No human ever approved the transaction.**

The only one that does all three.

Privacy projects stop at hiding votes. Agent projects stop at "the agent does stuff." ShadowKit is the rare build that **fuses sealed-until-close privacy, autonomous execution, and an on-chain spend lock** into a single loop — which is exactly why it targets three prize tracks at once.

A triple-track play

Engineered to satisfy **Main + Hack Agentic + Hack Privacy** simultaneously — one coherent product, three judging rubrics.

Trust math, not middlemen

No operator can peek at the tally. No human can mis-execute the result. The guarantees are **enforced by the chain**, not by policy or promise.

Built for Stellar's strengths

On-chain ZK (BLS12-381), **~zero fees** for per-call agent payments, fast finality, native USDC/XLM, and first-class custom-account auth.

Infrastructure, not a one-off

Ships as an **SDK + middleware** any Stellar DAO can adopt. ShadowDAO is the demo; the product is the toolkit beneath it.

THE ONE-LINE WEDGE

"Private voting is common. Autonomous agents are trendy. **ShadowKit is the first to make a sealed, private vote trigger an autonomous action that the blockchain itself guarantees can't go wrong.**"

Four audiences, four messages.

Who we're talking to — and the one line that lands for each. Use these to shape captions, deck slides, and outreach.

The DAO operator

TREASURY STEWARD · CORE TEAM

Runs a community treasury. Tired of governance theater and chasing multisig signers to act on decisions already made.

SAY TO THEM

Set the rules once; let private votes drive autonomous, bounded execution — no more 3am signing.

The Soroban builder

STELLAR DEV · INTEGRATOR

Wants private, autonomous governance in their app — but building ZK and agent safety from scratch is a months-long detour.

SAY TO THEM

Drop-in ZK + agent governance infrastructure. The hard cryptography is already done — you ship features.

The private voter

MEMBER · WHALE · TOKEN HOLDER

Won't vote because casting a ballot exposes their holdings and position to the whole market.

SAY TO THEM

Vote your conscience and your full weight — provably private, provably counted, impossible to front-run.

The evaluator

JUDGE · PRESS · ECOSYSTEM

Sees dozens of demos. Wants something that works end-to-end and pushes the ecosystem forward, not a slide-deck promise.

SAY TO THEM

A working, live hero loop that advances privacy and agentic execution on Stellar at the same time.

Taglines & key messages.

PRIMARY TAGLINE

Vote in the shadows. Execute in the light.

ALTERNATES

A Private votes. Autonomous execution. Zero middlemen.

B Sealed until close. Executed without you.

C Govern in private. Act on-chain. Trust the math.

D The vote stays secret. The agent does the rest.

ELEVATOR — SHORT

ShadowKit lets a DAO **vote in total privacy** — who, how, and how much, all hidden, the tally sealed until close — then an **autonomous AI agent executes the decision** on Stellar, unable to mispend a cent.

SAY THIS

- + "Private & **sealed-until-close**" — the unique angle
- + "**Autonomous** agent, **on-chain** safety lock"
- + "Infrastructure for **any** Stellar DAO"
- + "Math, not middlemen"

CORE VALUE PROPS (REPEATABLE LINES)

- **Truly private** — who, how, and how much, all hidden by zero-knowledge proofs.
- **Sealed until close** — no running tally, so whales can't time or swing it.
- **Self-executing** — an autonomous agent acts the moment voting ends.
- **Mathematically safe** — the chain blocks any move the vote didn't approve.

BOILERPLATE "ABOUT"

ShadowKit is zero-knowledge, AI-agent governance infrastructure for Stellar. Members vote privately with the result sealed until the deadline; an autonomous agent then executes the outcome on-chain, bounded by a policy enforced by the blockchain itself. Built at Build On Stellar, IBW 2026.

AVOID

- Claiming production-grade / audited security (it's a prototype)
- "Just private voting" — it buries the agent
- Heavy jargon (Groth16, nullifiers) in **headlines**
- Generic "blockchain voting app" framing

A starting point — your instincts lead.

The name, mood, palette, and marks below are a springboard, not a spec. They capture the feeling; you make it sing.

NAME & MEANING

Shadow = privacy, the unseen, votes cast in the dark. **Kit** = a developer toolkit, infrastructure you build with. The product's whole arc is **shadow** → **light**: sealed, then revealed and executed.

Plain-language glossary & fast facts.

So you're never lost in a technical conversation. Everything you need to speak about ShadowKit with confidence.

GLOSSARY

Zero-knowledge proof (ZK)

Prove something is true without revealing the secret — e.g. "I'm eligible and my vote is valid" without showing who you are or how you voted.

Nullifier

A one-time anonymous "I voted" token that prevents double-voting without revealing who voted.

Soroban

Stellar's smart-contract platform — the on-chain programs that enforce the rules.

Smart-account policy

The on-chain rulebook that mathematically limits what the agent is allowed to spend.

Timelock encryption

A digital lock that can only be opened after a set time. Used to seal the vote tally until the deadline.

Quorum

The minimum participation and agreement needed for a proposal to officially pass.

The agent

An AI program that executes the approved decision on-chain, strictly bounded by policy.

x402

A protocol for tiny pay-per-call payments — how the agent buys live market data.

How to use this brief: Everything here is a foundation, not a fence. The strategy, the angles, and the words are yours to reshape — lean on the privacy → reveal → autonomy story, keep the tone premium and confident, and let the design carry the "quiet power" of something that works without anyone watching.
